Health Risk Behaviors of Kansans
2011

State of Kansas
Sam Brownback, Governor

Kansas Department of Health and Environment
Dr. Robert Moser, Secretary

Report Preparation:
Pratik Pandya, MPH
Advanced Epidemiologist
Bureau of Health Promotion (BHP)

Report Supervision:
Ghazala Perveen, MBBS, PhD, MPH
Director of Science and Surveillance/Health Officer II
Bureau of Health Promotion (BHP)

Project Funding:
Partial funding for the 2010 Behavioral Risk Factor Survey was provided by cooperative agreements 1U58SO000008-02 from the Centers for Disease Control and Prevention, Atlanta GA.

BRFSS Overview

The Behavioral Risk Factor Surveillance System (BRFSS) is a random digit dial telephone survey of non-institutionalized adults age 18 years and older. If applicable, adult respondents also provide limited data on a randomly selected child in the household via surrogate interview. The BRFSS is coordinated and partially funded by the Centers for Disease Control and Prevention and is the largest continuously conducted telephone survey of population health risk in the world. It is conducted in every state, the District of Columbia, and several United States territories. The first BRFSS survey in Kansas was conducted as a point-in-time survey in 1990. Kansas has conducted the BRFSS survey annually since 1992.

The overall goal of the BRFSS is to develop and maintain the capacity for conducting population-based health risk surveys via telephone in Kansas. BRFSS data are used for the following:

- Monitoring the leading contributors to morbidity and premature death
- Tracking health status and assessing trends
- Measuring public knowledge, attitudes, and opinions
- Program planning
  - Needs assessment
  - Development of goals and objectives
  - Identification of target groups
- Policy development
- Evaluation of public health programs

Data from BRFSS are weighted to account for the complex sample design and non-response bias such that the resulting estimates will be representative of the underlying population as a whole as well as for target subpopulations.

Changes in BRFSS survey methodology

In recent years, the proportion of U.S. households with only cellular telephone (cell phone) service has been rising steadily. The increase has been more rapid since 2009. More than 3 of every 10 American households (31.6%) had only cell phone service during the first half of 2011. In the first half of 2003 cell phone only service was only 3 percent. The percentage of households with both landline and cell phone service, receiving all or almost all calls on the cell phone is also increasing. In 2011, nearly 1 of every 6 U.S. households (16.4%) with dual phone service received all or almost all calls on cell phones. The demographic characteristics of adults living in cell phone only service households are different. These adults are more likely to be: young, males, Hispanics, non Hispanics African Americans, living alone or with unrelated adults, living in poverty or near poverty, and renting a home. These
changes in phone use represent a threat to the validity of traditional Random Digit Dialing landline phone surveys such as the BRFSS.

To maintain representativeness, coverage and validity of data, changes in the survey methodology were made beginning in 2011. These changes include:

1. Use of dual frame sampling method (landline and cell phone samples) instead of single frame method (landline phone sample). The sample includes:
   - Adults 18 years and older living in a private residence with landline phone service
   - Adults 18 years and older living in a private residence with cell phone only service (at least 20% of total sample of complete interviews)

2. Use of the Iterative Proportional Fitting weighting method (Raking method) in place of the post stratification weighting method to improve the weighting, adjustment and estimation methods. The raking method adjusted the survey sample for age, sex, race and ethnicity, education level, marital status, home ownership and telephone type (landline/cell) to increase the representativeness of survey estimates for the general population.

Impact of New Survey Methodology on 2011 BRFSS Prevalence Estimates of Health Indicators

Changes in the 2011 BRFSS methodology will influence the state and national-level prevalence estimates for 2011 and subsequent years. Size and direction of the effect of new methodology on the prevalence estimates varies by health indicators. Changes in the 2011 data are likely to show indications of somewhat higher occurrences of risk behaviors common to younger adults and to certain racial or ethnic minority groups. The absolute increases or decreases in the prevalence estimates of health indicators from 2010 to 2011 BRFSS do not show any real changes in the actual prevalence of diseases, risk factors/behaviors and other health indicators in the general population. These variations in the estimates are caused by the addition of cell phone households to the survey sampling frame and adoption of a new advanced statistical method for weighting of the survey data. Comparisons cannot be made between the prevalence estimates of the health indicators generated for the previous years and those generated for 2011. The 2011 data cannot be compared to data from 2010 and preceding years to examine trends as prevalence estimates cannot be compared and interpreted using data generated from two different methodologies. The 2011 estimates will constitute a new baseline for monitoring trends of health indicators in subsequent years.

Analysis, Interpretation and Use of 2011 Kansas BRFSS Data

For analysis, the 2011 Kansas BRFSS dataset cannot be combined with those from previous years as sampling and weighting methods are different. Continue using weighted data analysis techniques for analysis of 2011 data. Interpretation of prevalence estimates has not changed. 2011 BRFSS provides prevalence estimates of diseases, risk factors/behaviors and other health indicators for
adult Kansans 18 years and older. 2011 BRFSS also provides prevalence estimates of health indicators for various socio-demographic subgroups in Kansas. The prevalence estimates from 2011 Kansas BRFSS are representative of non-institutionalized adults’ ages 18 years and older living in private residences with landline and/or cell phone service.

2011 BRFSS data can be reliably used for: examining burden of public health issues in Kansas, planning and evaluation of public health programs to address these issues, public health decision making, leveraging funding opportunities and public education.

The 2011 survey consisted of 224 questions and took an average of 25 minutes to complete. Survey topics on the 2011 Kansas BRFSS core section included: health status, healthy days, health care access, hypertension awareness, cholesterol awareness, chronic health conditions, tobacco use, demographics, fruits and vegetables, exercise, disability, arthritis burden, seatbelt use, immunization, alcohol consumption, prevention counseling for alcohol use, falls, seatbelt use, drinking and driving, women’s health, prostate cancer screening, colorectal cancer screening, HIV/AIDS. The state-added and CDC optional modules included average hours worked, breast cancer screening, pre-diabetes, diabetes, diabetes assessment, actions to control high blood pressure, heart attack and stroke, tobacco related issues, chronic obstructive pulmonary disease, doctor advised smoking cessation, fruit and vegetable tax, arthritis management, anxiety and depression, depression treatment, inadequate sleep, tetanus diphtheria (adults and adolescent) , oral health, disability barrier to attend work or school, veterans’ health, suicide, sexual violence, random child selection, childhood immunization, childhood diabetes, and childhood asthma.

2011 BRFSS survey also included questions on influenza related illness, an emerging health issues for adults and children during the months of January through April.

Summary of Leading Health Indicators

Healthy People 2020 is a comprehensive nationwide set of goals and objectives related to health promotion and disease prevention. In Healthy People 2020, a set of Leading Health Indicators were selected based on their relevance to broad public health topics and availability of data to measure their progress. They serve as a snapshot of the nation’s progress towards improving overall health status of the population.

The 12 Leading Health Indicators are:

- Access to Health Services
- Clinical Preventive Services
- Environmental Quality
- Injury and Violence
- Maternal, Infant, and Child Health
- Mental Health
- Nutrition, Physical Activity, and Obesity
- Oral Health
- Reproductive and Sexual Health
- Social Determinants
- Substance Abuse
- Tobacco

This document contains data on seven of the Leading Health Indicators, which are measurable using Kansas Behavioral Risk Factor Surveillance (BRFSS).

For more information about Healthy People 2020, please visit [http://www.healthypeople.gov/2020/default.aspx](http://www.healthypeople.gov/2020/default.aspx)

Access to health services is one of leading health indicators of Healthy People 2020. The United States Institute of Medicine (IOM) defined access as the timely use of personal health services to achieve the best possible health outcomes. Lack of access to health services is a persistent barrier to good health. Adults with no or limited insurance coverage are less likely to get needed medical attention.

Overall, indicators of access to health care estimated by Kansas BRFSS are insurance coverage, medical cost, and having a personal health care provider.

In 2011, an estimated 17% of adults 18 years and older had no health care coverage, including health insurance, prepaid plans such as HMOs, or government plans such as Medicare.

Source: 2011 Kansas Behavioral Risk Factor Surveillance System, Bureau of Health Promotion, KDHE.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
Prevalence of obesity was significantly higher among Non-Hispanic African-Americans (41.9%, 95% CI: 37.2-46.7) as compared to Non-Hispanic Whites (29.0%, 95% CI: 28.1-29.9).

Percentage of adults with no health care coverage significantly decreased with increase in age.

The percentage of no health care coverage among adults aged 18-24 years was significantly lower than that of 25 years and older adults.
Percentage of adults with no health care coverage significantly decreased with increase in the levels of education attainment.

About 1 in 3 (36.9%, 95% CI: 33.4-40.4) adults with less than high school education did not have health care coverage as compared to more than 1 in 16 (6.4%, 95% CI: 5.6-7.1) with college or higher level education.

About 1 in 3 (38.1%, 95% CI: 34.6-41.7) adults with an annual income of less than $15,000 did not have health care coverage as compared to more than 1 in 31 (3.2%, 95% CI: 2.6-3.8) with an annual income of $50,000 or higher.

Percentage of adults with no health care coverage among those who were out of work (51.5%, 95% CI: 47.4-55.5) was significantly higher than adults who were employed for wages or self-employed (15.9%, 95% CI: 14.9-16.8).

- About 1 in 5 adults with current asthma did not have health care coverage.
- About 14% of adults living with a disability did not have health care coverage.
- In the past 12 months, about 1 in 7 (14.3%) adults could not see a doctor when needed because of cost.

**Summary**

An estimated 17% of adults 18 years and older had no health care coverage (health insurance, prepaid plans such as HMOs or government plans such as Medicaid). A significantly higher percentage of males did not have health care coverage than females. A significantly higher percentage of Hispanics and
Non-Hispanic African-Americans did not have health care coverage as compared to Non-Hispanic White adults. Lower education and annual household income levels had significant influences on whether a person had health care coverage or not. The percentage of adults who had no health care coverage decreased with an increase in annual household income, a higher education level and age. A significantly higher percentage of adults with out of work status did not have health care coverage as compared to employed for wages or self-employed adults.

The Healthy People 2020 target for the access to health care objective was to increase the proportion of persons with health insurance to 100%. As 17% of adults in Kansas have no health insurance, further public health efforts are needed to reach the target in Kansas.
Access to Health Care -
No Personal Health Care Provider

No Health Care Provider-A barrier for health care access: The 2011 Kansas BRFSS included a question to assess whether Kansas adults have one person that they thought of as their personal doctor or health care provider.

This indicator is a very important access to health care measure because access to primary health care and having a personal doctor has shown to substantially improve health-related outcomes. People who have a personal health care provider also indicate that they receive appropriate preventive care, have their problems identified and pay lower costs related to hospitalization due to timely diagnostic tests, fewer prescriptions and emergency room visits \(^3\).

- About two in five (19.7%) adults did not have any one that they think of as their personal doctor or health care provider.
- More than 8 in 10 adults (80.3%) had one or more person(s) as their personal doctor or health care provider.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
No Personal Doctor by Specific Subpopulations

A significantly higher percentage of Non-Hispanic African-American adults (31.0%, 95% CI 26.6-35.3) did not have a personal doctor or health care provider as compared to Non-Hispanic Whites (12.4%, 95% CI 11.2-13.7).

Almost 1 in 3 Hispanic adults (36.3%) did not have a personal doctor or health care provider as compared to 1 in 5 Non-Hispanic White adults (17.2%).

A significantly higher percentage of males (25.7%, 95% CI: 24.3-27.0) did not have a personal doctor or health care provider as compared to females (14.0%, 95% CI: 13.1-14.0).
About 1 in 3 adults among age groups 18-24 years, and 25-34 years did not have a personal doctor or health care provider.

About 1 in 21 adults (4.7%) ages 65 years and older did not have a personal doctor or health care provider.

Percentage of adults with no personal doctor or health care provider decreased with increase in age.

About 1 in 3 adults with less than high school education (36.2%) did not have a personal doctor or health care provider.

About 1 in 10 adults with college or higher level of education (12.5%) did not have a personal doctor or health care provider.

About 1 in 3 adults with annual household income less than $15,000 (34.0%, 95% CI: 30.4-37.5) did not have a personal doctor or health care provider.

About 1 in 10 adults with annual household income $50,000 or more (10.7%, 95% CI: 9.7-11.7) did not have a personal doctor or health care provider.

A significantly higher percentage of those with a lower annual household income did not have a personal doctor.

About 1 in 3 adults (39.0%) among those that were out of work did not have a personal doctor or health care provider as compared to about 1 in 4 adults (21.8%) among those that were employed for wages or self-employed.
Summary

Not having a personal doctor or a health care professional is a barrier to access to health care. About 1 in 5 adults did not have anyone that they thought of as a personal doctor or health care provider. A significantly higher percentage of males, young adults, adults with lower annual household income and education did not have a personal doctor or health care professional. The percentage of adults with no personal doctor or health care provider was significantly higher among adults who were out of work as compared to adults that were self-employed or employed for wages.

One of the Healthy People 2020 objective is to increase the proportion of persons who have a specific source of ongoing primary care to 96%. As 19.7% of adults in Kansas do not have a personal health care provider, further public health efforts are needed to reach HP2020 target in Kansas.
Population assessment of obesity is done by calculating Body Mass Index (BMI). Categories of BMI indicate ranges of body weight. Obesity has physical, psychological, and social consequences in adults. Health risks of obesity includes coronary heart disease, stroke, hypertension, dyslipidemia, arthritis and type-2 diabetes. Apart from physical ailments, people suffering from obesity also face psychological problems including depression, appearance consciousness, and lack of self confidence.

**BMI Categories**

- **Normal/Underweight**: BMI less than 25 kg/m²
- **Overweight**: BMI 25 kg/m² to 29.9 kg/m²
- **Obese**: BMI equal to or more than 30 kg/m²

The Kansas BRFSS survey included questions about respondents’ height and weight; categories of weight status were calculated for each respondent. In 2011, 29.6% (95% C.I: 28.7-30.4) of Kansas adults 18 years and older were obese.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
Obesity by Specific Subpopulations

- Prevalence of obesity was significantly higher among Non-Hispanic African-Americans (41.9%, 95% CI: 37.2-46.7) as compared to Non-Hispanic White (29.0%, 95% CI: 28.1-29.9).

- About 30.0% (95% CI: 28.8-31.3) of males and 29.1% (95% CI: 28.0-30.1) of females were obese.

- About 1 in 3 adults among age groups 35-44 years, 45-54 years and 55-64 years were obese.

- 1 in 4 adults (26.3%) ages 65 years and older was obese.
Adults with less than college graduation had a significantly higher prevalence of obesity as compared to adults with a college graduation.

Adults with an annual household income of $50,000 or more had significantly lower prevalence of obesity as compared to other income status categories.

About 1 in 2 adults (46.7%) among those that were unable to work were obese as compared to about 1 in 3 adults (29.9%) among those that were employed for wages or self-employed.

</table>

About half of the adults with diabetes (57.0%) were obese.
About 2 in 5 adults living with disability, current asthma or arthritis were obese.
Obesity is highly prevalent among adults with chronic conditions.

Summary
In 2011, about one-third of the population was obese. Although high prevalence of obesity was observed among most of the population subgroups, it was significantly higher among Non-Hispanic African-Americans. Adults whose annual household income was less than $50,000 and adults who had other chronic conditions such as diabetes, arthritis, current asthma or living with a disability also had
high prevalence of obesity. Adults who are unable to work had higher prevalence of obesity as compared to adults who are employed.

The Healthy People 2020 target for the obesity objective is to reduce the proportion of adults who are obese to 30.6%. Though the Kansas estimate of 29.6% is close to the HP 2020 target, public health efforts are still needed to further reduce the percentage of Kansans who are obese.
One of the leading modifiable (controllable) risk factors for heart disease and stroke is hypertension\(^8\). Moreover, adults with hypertension are at higher risk for heart disease, stroke, congestive heart failure and end-stage renal disease\(^9\). One of the objectives of Healthy People 2020 is to reduce the proportion of adults with hypertension. High blood pressure affects approximately one in three adults in the United States, and more than half of Americans with high blood pressure do not have it under control\(^10\).

In 2011, 30.8% (95% C.I: 30.1-31.6) of Kansas adults 18 years and older had hypertension (high blood pressure).

About half of the adults with arthritis (54.4%) had hypertension.
About 71% of the adults with diabetes had hypertension.
About 1 in 3 adults with current asthma had hypertension.
About half of the adults living with a disability (50.2%) had hypertension.
Hypertension was highly prevalent among adults with chronic conditions.
Summary

In 2011, about one in three (30.8%) adults 18 years and older had hypertension. A higher prevalence of hypertension was seen among Non-Hispanic African Americans. Prevalence of hypertension was statistically higher among older adults, adults with less than college graduation and with lower income. Adults who are unable to work had higher prevalence of hypertension as compared to those that were employed for wages or self-employed. Hypertension is highly prevalent among adults with chronic conditions such as diabetes, arthritis and adults living with a disability.

The Healthy People 2020 target for the hypertension objective is to reduce the proportion of adults with hypertension to 26.9%. As 30.8% of adults in Kansas have hypertension, further public health efforts are needed to reach the target in Kansas.
Diabetes is the leading cause of kidney failure, non-traumatic lower limb amputations, and new cases of blindness among adults in the United States. Diabetes is a major cause of heart disease and stroke. Diabetes is the seventh leading cause of death in the United States. 11

Risk factors for type 2 diabetes include obesity, family history of diabetes, prior history of gestational diabetes, impaired glucose tolerance and physical inactivity 12.

The Healthy people 2020 goal for diabetes is to reduce the disease and economic burden of Diabetes Mellitus and improve the quality of life for all persons who have, or at risk for diabetes mellitus 13.

In 2011, 9.5% (95% C.I: 9.1-10.0) of Kansas adults 18 years and older had diabetes.

Summary

About one in ten (9.5%) Kansas adults in the population had diabetes in 2011. Prevalence of diabetes increased with age, with 1 in 5 adults among age groups 65 years and older having diabetes. Prevalence of diabetes was significantly higher among Non-Hispanic African-Americans. Adults with annual household income less than $50,000 and adults with other chronic conditions such as arthritis, current asthma or living with a disability also had high prevalence of diabetes. Adults who were unable to work, retired or out of work had higher prevalence of diabetes as compared to adults who were employed.
Motor vehicle accidents are the leading cause of death for people age 5 – 34. It can lead to premature death, disability, poor mental health, high medical cost and lost productivity. The most effective way to reduce injuries and mortality due to accidents is the use of seat belts. Increasing use of safety belts is one of the objectives for the prevention of unintentional injury. The Healthy People 2020 goal for injury prevention is to prevent unintentional injuries, and reduce their consequences.

In 2011, 19.4% (95% C.I: 18.6-20.1) of Kansas adults 18 years and older did not always wear a seatbelt when they drive or ride in a car.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
**Percentage of Adults Who Did Not Always Wear a Seatbelt When They Drive or Ride in a Car by Specific Subpopulations**

Percentage of adults 18 years and older who did not always wear a seatbelt was not significantly different by race/ethnicity.

Prevalence of not always wearing a seatbelt was higher among males 25.5% (95% C.I: 24.3-26.8) than females 13.4% (95% C.I: 12.6-14.3).
Prevalence of not always wearing a seatbelt was significantly higher among adults ages 18-24 years 27.1% (95% C.I: 23.8-30.3) as compared to adults ages 65 years and older 15.1% (95% C.I: 14.1-16.2).

Prevalence of not always wearing a seatbelt was significantly higher among adults with less than college graduation as compared to adults with a college graduation.

A significantly lower percentage of adults with an annual household income of $50,000 or more did not always wear a seatbelt as compared to other income groups.

About 1 in 4 adults (23.6%) among those that were out of work did not always wear a seatbelt when they drive or ride a car as compared to about 1 in 7 adults (13.6%) among those that were retired.
Summary

About one in five Kansas adults did not always wear a seatbelt when they drove or rode in a car. Not always wearing a seatbelt while driving was significantly higher among young adults (18-24 years), males, and adults with less than high school education. A significantly higher percentage of adults with annual household income lower than $50,000 did not always wear a seatbelt while driving.

The target set by Healthy People 2020 is to increase the use of safety belts to 92.4%. As 19.4% of adults in Kansas do not always wear a seatbelt, further public health efforts are needed to reach this target in Kansas.
Recommended Level of Physical Activity

Regular physical activity can improve people’s overall health and reduce various risks for morbidity and mortality due to a sedentary lifestyle. Studies show that routine physical activity exerts enormous benefits for the prevention of chronic conditions like diabetes mellitus, cardiovascular disease, obesity, cancer, musculoskeletal diseases, and depression.\(^\text{16}\)

In 2008, the US Department of Health and Human Services released updated physical activity guidelines for Americans. According to these guidelines, adults who participate in moderate physical activities for at least 150 minutes per week, vigorous physical activities for at least 75 minutes per week or an equivalent combination of moderate and vigorous physical activities and also participate in muscle strengthening activities on two or more days per week would meet the recommended level of physical activity\(^\text{17}\).

An estimated 83.5% of adult Kansans did not meet both the aerobic and strengthening components of the new physical activity guidelines.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.

### Did Not Participate in Recommended Aerobic and Strengthening Activities by Specific Subpopulations

**Percentage of Adults Who Did not Participate in Recommended Aerobic and Strengthening Activities by Race/Ethnicity**

- **White, Non-Hispanic**: 83.3%
- **African American, Non-Hispanic**: 83.4%
- **Other/Multi-Race, Non-Hispanic**: 80.2%
- **Hispanic**: 85.5%
About four out of five adults did not participate in both the recommended aerobic and strengthening activities among all race/ethnicity subgroups. There was no difference by race/ethnicity subgroups.

About 84.8% females (95% C.I: 83.9-85.7) did not participate in recommended level of aerobic and strengthening activities as compared to 82.1 males (95% CI: 80.9-83.2).

Recommended level of physical activity decreased with increasing age.

Almost 9 in 10 adults age 65 years and older (87.3%) did not participate in recommended level of physical activity.

About 9 in 10 adults with less than high school education (44.8%) did not participate in recommended level of physical activity.

The percentage of adults not participating in recommended level of physical activity was higher among those with less than high school education (89.5%, 95% CI: 86.9-92.1) as compared to those with college or more education (76.9%, 95% CI: 75.7-78.2).
Percentage of adults not participating in recommended level of physical activity was high among adults with a lower annual household income.

About 9 in 10 adults (88.9%) with an annual household income less than $15,000 did not participate in recommended level of physical activity.

Among adults who are unable to work, 91.3% did not participate in recommended level of physical activity.

Percentage of non-participation in recommended level of physical activity was high among adults with co-morbid condition.

More than 9 in 10 adults having diabetes (92.5%) did not participate in recommended level of physical activity.

About 88.2% adults with arthritis or 85.0% with current asthma did not participate in recommended level of physical activity.

Summary

About one-fifth (16.5%) of the adult Kansans participated in the recommended level of physical activity. The percentage of adults who did not meet the recommended level of physical activity was highest among 65 years and older adults. Percentage of adults who did not meet the recommended level of physical activity was higher among females, adults with a low annual household income and education status. Higher percentage of adults who did not meet the recommended level of physical activity was seen among people with other chronic conditions, such as arthritis and diabetes. A higher percentage of non-participation in leisure time physical activity was seen among adults who are unable to work.

One of the leading health indicators for Healthy People 2020 is to increase the proportion of adults who meet the objectives for aerobic physical activity and for muscle-strengthening activity to 20.1%. As only 16.5% met the recommended level of physical activity, further public health efforts are needed to reach this target in Kansas.
Oral health is an essential and integral component of overall health throughout life and is much more than just healthy teeth. Oral refers to the whole mouth, including the teeth, gums, hard and soft palate, linings of the mouth and throat, tongue, lips, salivary glands, chewing muscles, and upper and lower jaws. Not only does good oral health mean being free of tooth decay and gum disease, but it also means being free of chronic oral pain conditions, oral cancer, birth defects such as cleft lip and palate, and other conditions that affect the mouth and throat.

Oral health and general health status are interrelated. Oral infections in the mouth such as periodontal (gum) diseases may increase the risk of heart disease, may put pregnant women at greater risk of premature delivery, and may complicate control of blood sugar for people living with diabetes.

Risk factors such as tobacco use and poor dietary practices affect oral health. One of the leading health indicators of Healthy People 2020 is to increase the proportion of adults who used the oral health care system in the past year.

- About 36.3% of the adult 18 years and older did not have any kind of dental insurance coverage.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
No Dental Insurance by Specific Subpopulations

Prevalence of no dental insurance was significantly higher among Hispanics (44.7%, 95% CI: 37.0-52.5) as compared to Non-Hispanic White (32.0%, 95% CI: 30.2-33.9) and Non-Hispanic Other/Multi-Race (27.5%, 95% CI: 21.8-33.2).

About 1 in 3 males (34.2%) and about 4 in 10 females (38.3%) had no dental insurance.
About half of the adults (56.3%, 95% CI: 48.2-64.4) with less than high school education had no dental insurance as compared to more than one in four adults (24.0%, 95% CI: 21.8-26.1) with college or higher level education.

About 7 in 10 adults (72.5%, 95% CI: 64.8-80.3) with annual household income less than $15,000 had no dental insurance as compared to more than 1 in 6 adults (16.0%, 95% CI: 14.2-17.7 with annual household income $50,000 or more.

Percentage of no dental insurance among ages 65+ was significantly higher than younger age groups.

</table>
Currently, about one-third (36.3%) of the population did not have any dental insurance. A significantly higher percentage of Hispanics did not have dental insurance. Percentage of not having dental insurance was significantly higher among ages 65+ than younger age groups. Percentage of adults with dental insurance increased with an increase in educational status and annual household income. Higher percentage of adults with other chronic conditions such as diabetes, arthritis, current asthma or living with a disability did not have dental insurance. A higher percentage of adults who were unable to work or are out of work did not have dental insurance as compared to adults who were employed.

One of the leading health indicators for healthy people 2020 is to increase the proportion of adults who used the oral health care system in the past year to 49.0%. One of the main reasons cited by Kansas adults for not accessing dental care is lack of dental insurance. Only 36.3% of Kansans did not have any dental insurance in 2011.
Alcohol consumption is the third leading preventable cause of death in the United States.\textsuperscript{20} Alcohol abuse is generally measured by two types of alcohol consumption patterns: binge and heavy drinking. Binge drinking is defined as adult males having five or more drinks on one occasion and adult females having four or more drinks on one occasion in the past 30 days. It is associated with alcohol poisoning, unintentional injuries, suicide, hypertension, pancreatitis, sexually transmitted diseases, and meningitis, among other disorders. The National Institute on Alcohol Abuse and Alcoholism reported that binge drinking underlies many negative social costs, including interpersonal violence, drunk driving, and lost economic productivity.\textsuperscript{21}

One of the leading health indicators of the Healthy People 2020 is to reduce the proportion of adults aged 18 years and older engaging in binge drinking during the past 30 days.\textsuperscript{22}

- In 2011, the prevalence of binge drinking was 17%.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
Binge Drinking by Specific Subpopulations

About 1 in 6 Non-Hispanic White adults (18.0%) and Hispanic adults (17.7%) engaged in binge drinking. No significant difference was seen in binge drinking among race and ethnicity subgroups.

The prevalence of binge drinking among males was 23.1% (95% CI: 21.8-24.3).

The prevalence of binge drinking among females was 11.2% (95% CI: 10.4-12.1).

A significantly higher percentage of males were binge drinkers than females.
About 1 in 4 adults (28.3%) ages 18-24 years were engaged in binge drinking.

About 1 in 5 adults (18.5%, 95% CI: 17.1-19.9) with some college education were engaged in binge drinking.

About 1 in 5 adults (19.5%, 95% CI: 18.3-20.7) with an annual household income of $50,000 or higher were engaged in binge drinking.
Table 2. Binge drinking among adults aged 18 years and older by co-morbid conditions in Kansas, 2011 BRFSS

The prevalence of binge drinking among adults who are employed for wages or self-employed was 21.1%, (95% CI: 20.1-22.2).

The prevalence of binge drinking among adults who are unable to work was 5.2%, (95% CI: 3.3-7.0).
More than 1 in 3 current smokers (28.8%) and about 1 in 5 adults (19.1%) whose mental health was not good for 14 or more days in past 30 days did binge drinking.

**Summary**

In 2011, prevalence of binge drinking was 17%. Males and younger adults had a high prevalence of binge drinking. Current smokers, adults whose mental health was not good for 14 or more days in the past 30 days and adults with current asthma had high prevalence of binge drinking.

The Healthy People 2020 target for the substance abuse objective was to reduce the proportion of adults engaging in binge drinking of alcoholic beverages during the past month. As 17% of adults in Kansas are binge drinkers of alcoholic beverages during the past month, further public health efforts are needed to address this issue.
Tobacco use is one of the most preventable causes of morbidity and mortality. More deaths are caused each year by tobacco use than by all deaths from human immunodeficiency virus (HIV), illegal drug use, alcohol use, motor vehicle injuries, suicides, and homicides combined. Reducing the prevalence of cigarette smoking is one of the most important public health goals because of the strong association of tobacco use with diseases and premature mortality. At present, nearly 40 diseases or causes of death are known to be positively associated with cigarette smoking. Smoking causes many types of cancers including lung cancer, coronary heart disease, stroke, peripheral vascular disease, emphysema, bronchitis, chronic airway obstruction etc. Cigarette smoking has many adverse reproductive and early childhood effects, including increased risk for infertility, stillbirth, and low birth weight.

One of the leading health indicators of Healthy People 2020 is to reduce cigarette smoking by adults. 2011 BRFSS data defines current smokers as adults who have smoked 100 cigarettes in their entire life and smoke now, either every day or some days.

- About 1 in 5 adults (22.0%) currently smokes cigarettes.
- About 1 in 5 adults (22.4%) is a former smoker.
- About 56% of adults have never smoked.
- More than half of current smokers (56.8%) tried to quit smoking for one day or longer in the past year.

The prevalence of current smoking was 22.0% and was higher among young and middle-aged adults. The prevalence was also decidedly higher among adults with a lower education status. It was also higher among adult with a lower annual household income. About 57.0% of current smokers had tried to quit smoking for one day or longer in the past year.

The Healthy People 2020 target for the tobacco use objective is to reduce cigarette smoking among adults to 12%. As 22% of adults in Kansas are current cigarette smokers, further public health efforts are needed to reach the target in Kansas.

**Summary**

About 3 in 10 adults living with a disability (27.7%) or with current asthma (29.4%) were current smokers.
Smokeless Use

One of the goals of Healthy People 2020 for tobacco use is to reduce illness, disability, death related to tobacco use. Smokeless tobacco causes a number of serious oral health problems, including cancer of the mouth and gums, periodontal disease, and tooth loss. The one of the objectives of Healthy People 2020 for tobacco use is to reduce use of smokeless tobacco products by adults. 29

2011 BRFSS data defines smokeless tobacco user as an adult who currently uses chewing tobacco, snuff or snus (Swedish for snuff) some days or every day.

About 5.3% of adults were smokeless tobacco users.

*Prevalence estimates for race and ethnicity were age-adjusted to the U.S. 2000 standard population.
Current Use of Any Smokeless Tobacco Products by Specific Subpopulations

**Percentage of Adults Who Currently Use Any Smokeless Tobacco Products by Race/Ethnicity**

- About 6% of Non-Hispanic Whites were current smokeless tobacco product users.
- About 2.2% of African American, Non-Hispanic were current smokeless tobacco product users.
- About 5.0% of Other/Multi-Race, Non-Hispanic were current smokeless tobacco product users.
- About 3.4% of Hispanic were current smokeless tobacco product users.

**Percentage of Adults Who Currently Use Any Smokeless Tobacco Products by Gender**

- About 1 in 10 adult males (10.1%, 95% CI: 9.2-11.0) and females (0.7%, 95% CI: 0.5-0.9) were current smokeless tobacco product users.
- The prevalence of current smoking was significantly higher in males than females.

**Percentage of Adults Who Currently Use Any Smokeless Tobacco Products by Age Groups**

- About 8.1% adults aged 25-34 years were current smokeless tobacco product users.
- Prevalence of smokeless tobacco use was higher among adults of younger age groups as compared to adults’ ages 65 years and older.
About 6.9% (95% CI: 6.0-7.8) of adults with less than high school education were smokeless tobacco product users.

About 3.1% (95% CI: 2.5-3.6) of adults with college or higher education were current smokeless tobacco product users.

Prevalence of smokeless tobacco products use was significantly higher among adults with less than high school education as compared to those with more education.

Smokeless tobacco use was similar in all income groups at around 5.0%.

A significantly higher percentage of adults who are employed for wages or self employed currently used smokeless products as compared to retired adults, homemakers or students.

Summary

The prevalence of current smokeless tobacco use was 5.3%. The prevalence of current smokeless tobacco use was higher among males, young and middle-aged adults. The prevalence is also higher among adults with a lower education status.

The Healthy People 2020 target for the tobacco use objective is to reduce use of smokeless tobacco products by adults to 0.3%. As 5.3% of adults in Kansas are currently using smokeless tobacco products, further public health efforts are needed to reach the target in Kansas.
METHODOLGY

Sampling
In 2011, the CDC advised all states and territories to implement a dual frame sampling methodology for BRFSS survey and to include both: adults 18 years and older living in private residences with landline telephone service; and adults 18 years and older living in private residences with cellular telephone only service. The states were advised to target at least 20 percent of their total sample of complete interviews to be from cellular telephone only service households. This change in sampling methodology of the BRFSS was made to address the impact of growing number of households with cellular telephone only service and differences in the demographic profile of the people who live in cellular telephone only service households and to maintain representativeness, coverage, and validity of BRFSS data.

The dual frame sampling methodology for 2011 survey included two components: 1) Landline telephone service survey component; and 2) Cellular telephone only service component.

The landline telephone survey component of this dual frame sampling method remained identical to the sampling method for 2009 and 2010 surveys. It was comprised of implementation of disproportionate stratified sampling methodology that included selection of landline telephone numbers within 10 geographic strata comprised of county grouping instead of random selection of telephone numbers from the entire state as a single geographic stratum. These 10 geographical strata include; Johnson county, Sedgwick county, Shawnee county, Wyandotte county, Northwest public health district, Southwest public health district, North Central public health district, South Central public health district excluding Sedgwick county, Northeast public health district excluding Johnson, Shawnee and Wyandotte counties, and Southeast public health district. The sample that was drawn from each geographical stratum was based on population size within each geographical stratum, the confidence level and the margin of error. The landline telephone component sampling was designed to reach non-institutionalized adults ages 18 years and older living in private residences in Kansas. As in previous years, this method of probability sampling involved assigning sets of one hundred telephone numbers with the same area code, prefix, and first two digits of the suffix and all possible combinations of the last two digits ("hundred blocks") into two strata. Those hundred blocks that had at least one known household number were designated high density (also called "one-plus blocks"); hundred blocks with no known household numbers were designated low density ("zero blocks"). The high density
stratum was sampled at a rate 1.5 times higher than the low density stratum, resulting in greater efficiency.

The cellular telephone survey component of this dual frame sampling method included the sampling frame comprised of all 1000-series blocks dedicated to cellular devices serving the state with a nonzero chance of inclusion. The cellular telephone survey component sampling was designed to reach non-institutionalized adults ages 18 years and older living in the private residences with cellular telephone only service in Kansas.

**Sample Size**
For 2011 Kansas BRFSS survey, the target total (combined landline and cell phone sample) sample size was about 19,200 complete interviews with a target of 16,000 complete interviews for the landline telephone survey component and 3,200 complete interviews for the cellular telephone survey component.

**Weighting Procedure**
Data weighting is an important statistical process that attempts to remove bias in the sample. It corrects for differences in the probability of selection due to non-response and non-coverage errors. It adjusts variables of age and gender between the sample and the entire population. Data weighting also allows the generalization of findings to the whole population, not just those who respond to the survey.

Once BRFSS data are collected, statistical procedures are undertaken to make sure the estimates of health indicators generated by the analysis of survey data are representative of the population for each state and/or local area.

This weighting process of BRFSS data includes calculation of design weight as one of its components: In the BRFSS survey, the design factors that affect weighting include the number of residential telephones in the household, number of adults in the household and geographic or density stratification. Weighting process of BRFSS also involves adjustment for the distribution of the sample data so that it reflects more accurately the total population of the sampled area. The method used for this adjustment through and including 2010 was the post-stratification method.

**Beginning with the 2011 dataset, the CDC has adopted the raking method in place of post stratification weighting procedure as the sole BRFSS statistical weighting method.**
The new BRFSS weighting methodology was comprised of two components:

- ✔ Design Weight
- ✔ Raking Adjustment
Design Weight: Design Weight was calculated by using computational formula:

\[
\text{Design Weight} = \_\text{STRWT} \times \left( \frac{1}{\text{NUMPHON2}} \right) \times \text{NUMADULT}
\]

- The stratum weight (\_STRWT) was calculated using:
  - Number of available records (NRECSTR) and the number of records selected (NRECSEL) within each geographic strata (\_GEOSTR) and density strata (\_DENSTR);
  - Geographic strata (entire state, counties, census tracts, etc.); and
  - Density strata (1=listed numbers, 2=not listed numbers).
- Within each \_GEOSTR * \_DENSTR combination: The stratum weight (\_STRWT) was calculated from the average of the NRECSTR and the sum of all sample records used to produce the NRECSEL.

The computational formula for stratum weight:

\[
\text{STRWT} = \frac{\text{NRECSTR}}{\text{NRECSEL}}
\]

- 1/ NUMPHON2 was the inverse of the number of residential telephone numbers in the respondent's household.
- NUMADULT was the number of adults 18 years and older in the respondent's household.

Final Weight was calculated for analysis of survey data to generate estimates for health indicators that were representative of the general population.

The computational formula for Final weight:

\[
\text{Final Weight} = \text{Design Weight} \times \text{Raking Adjustment}
\]

Raking adjustment: Raking adjusts estimates within each state by using:
- Telephone source,
- Detailed race and ethnicity,
- Regions within state,
- Education level,
- Marital status,
- Age group by gender,
- Gender by race and ethnicity,
- Age group by race and ethnicity, and
- Renter/homeowner status.

Raking was completed by adjusting for one demographic variable (or dimension) at a time. For example, when weighting by age and gender, weights were first adjusted for gender groups, then those estimates were adjusted by age groups. This procedure was continue in an iterative process until all group proportions in the sample approached those of the population, or were stopped after 75 iterations.
Weighted data analysis techniques were used to analyze 2011 BRFSS survey to generate population based estimates of health indicators. The Final weight variable was used in these analyses.

**Weight Trimming in Raking**

Weight trimming was used to increase the value of extremely low weights and decrease the value of extremely high weights. The objective of weight trimming was to reduce errors in the outcome estimates caused by unusually high or low weights in some categories.

**Data Reliability**

Telephone interviewing has been demonstrated to be a reliable method for collecting behavioral risk data and can cost three to four times less than other interviewing methods such as mail-in interviews or face-to-face interviews. The BRFSS methodology has been utilized and evaluated by the CDC and other participating states since 1984. Content of 2011 BRFSS survey questions, questionnaire design, data collection procedures, surveying techniques, and editing procedures had been thoroughly evaluated to maintain overall data quality and to lessen the potential for bias within the population sample.

**RESPONSE RATE**

The CASRO (Council of American Survey Research Organizations) response rate was used as a measure of quality of data. The 2011 Kansas BRFSS achieved a rate of 58.2% indicating reliable results. The CASRO formula was based on the number of interviews completed, the number of households reached, and the number of households with unknown eligibility status. The CASRO response rate was used because in addition to those persons who refused to answer questions, lack of response can also arise because household members were not available despite repeated call attempts, or household members refused to pick up the phone based on what they detect from caller ID.

**DATA ANALYSIS**

The weighted data analysis was conducted to estimate overall prevalence of the risk factors, diseases and behaviors among adults 18 years and older in Kansas. On some questions which pertain to a particular topic, only respondents who responded in a specific way [subpopulation] on an initial question continue to the next question. Though the subsequent question was asked from those respondents who responded in a particular manner on initial question, analysis for the subsequent question was based on the denominator that includes all respondents who responded to the initial question (in any manner). Therefore, the results presented were on all respondents vs. the subpopulation. Questions which have this approach applied were indicated with the statement "Denominator adjusted to represent the prevalence in the overall population". In addition to overall prevalence estimates, stratified analyses were also conducted to examine burden of a public health
issue within different population subgroups based on socio-demographic factors, risk behaviors and co-morbid conditions. In addition, data analysis was also conducted using population density groups. The definition and designations of these groups were described below:

The weighted data analysis techniques applied for the analysis of 2011 survey data were the same as in previous years. Adoption of new survey methodology for 2011 and subsequent years did not affect the analytical approach for BRFSS data analyses to generate estimates of the health indicators.

QUESTIONNAIRE DESIGN

The 2011 BRFSS survey conducted by all states consisted of a core section and optional modules/state-added questions section. The Core section of the survey was consistent across all states as this section included questions prescribed by the CDC. The optional modules were selected by the states from a bank of CDC-supported modules. Additionally, each state designed its own modules (state-added modules). The 2011 Kansas BRFSS used a split questionnaire design. It consisted of the core section, which was asked of all respondents and then the survey splits into two “branches” of optional modules/state-added modules. Once respondents had been asked the core questions, they were either asked questions in questionnaire A (also called Part A) or questionnaire B (also called Part B) of the survey. Respondents were randomly assigned to one of these two arms of the survey. Approximately half of the respondents received questionnaire A and the remaining received questionnaire B.

Advantages of the 2011 survey split questionnaire:
- Collected data on numerous topics within one data year
- Collected in-depth data on one specific topic
- Kept the interview time and questionnaire length to a minimum

Disadvantages of the 2011 survey split questionnaire:
- Added to the complexity of data weighting; additional weighting factors were needed
- Variables on questionnaire A could not be analyzed with variables on questionnaire B

Analysis of the 2011 survey split questionnaire:
The sample size for each split of the questionnaire was approximately half of the total sample size. As mentioned above, each respondent was randomly assigned to questionnaire A or to questionnaire B. The questions regarding certain conditions were included in the core section (e.g., asthma, disability, high blood pressures, etc.). State added questions and optional modules for these conditions were included on questionnaire A or questionnaire B. Therefore, these additional questions on a specific health condition were asked to the respondents who were assigned to that particular split questionnaire. This resulted in approximately half of the respondents who had a particular condition from the core section respond to additional questions on the specific condition.
Also, the number of adults with the specific health condition might vary on each question due to respondents terminating at various points in the survey.

TYPES OF QUESTIONS ON THE BRFSS

The 2011 BRFSS questionnaire was designed by the Centers for Disease Control and Prevention, state BRFSS Coordinators, and each individual state’s survey selection committee. The questionnaire had three components: core questions, optional modules, and state added questions.

- **Core questions** were asked by all states and included approximately 97 questions (though this may vary somewhat from year to year). The order the questions appear and the wording of the question was exactly the same in all states. Types of core questions included fixed, rotating, and emerging health issues.
  - Fixed core: contains questions that were asked every year. Fixed core topics included 71 questions on health status, health care access, healthy days, disability, demographics, tobacco use, alcohol use, seatbelt use, exercise, immunization, HIV/AIDS, chronic health conditions.
  - Rotating core: Included questions that were asked every other year. The 2011 survey included 16 rotating core questions on fruits and vegetables, hypertension awareness, cholesterol awareness, and arthritis burden.
  - Emerging Health Issues: The 2011 survey included 10 questions on late breaking health issues.

- **Optional Modules** included questions on a specific health topic. The CDC provided a pool of questions from which states may select. States had the option of adding these questions to their survey. The CDC's responsibilities regarding these questions included development of questions, cognitive testing, financial support to states to include these questions on their questionnaire, data management, limited analysis and quality control. The optional modules included in 2011 Kansas BRFSS survey were comprised of questions on random child selection, childhood asthma, pre-diabetes, diabetes, actions to control high blood pressure, heart attack and stroke, chronic obstructive pulmonary disease, arthritis management, anxiety and depression, inadequate sleep, tetanus diphtheria (adults), childhood immunization, and veterans health.

- **State-added questions** were based on public health needs of each state. In 2011 Kansas BRFSS survey, state added modules included questions on average hours worked, breast cancer screening, childhood diabetes, diabetes assessment, tobacco related issues, doctor advised smoking cessation, fruits and vegetables tax, depression treatment, tetanus diphtheria (adolescents), oral health, disability barrier to attend work or school, suicide, and sexual violence.
LIMITATIONS

Sampling
The BRFSS survey sampling methods were discussed in the methodology section. Sampling yielded results which were an estimate of the true answer for the entire population. The higher the number of persons interviewed, the greater the precision of the estimate. When the data were subdivided to look at sub-populations (e.g., an age subgroup) these estimates might be less precise; if the number of persons interviewed was small because the subgroup represents a small fraction of the population (e.g., diabetics less than 30 years old), the estimate might become too uncertain to be of value. Because the survey was conducted by telephone, persons without telephones could not be reached. Since phone ownership was highly correlated to income, persons without a phone were more likely to have low incomes than persons with a telephone. This might affect questions with responses that were highly dependent on income (e.g., health insurance) more than other questions. However, because phone ownership was high in Kansas (greater than 95%), it was unlikely that failing to reach these persons would substantially alter results.

From 2011 onwards, inclusion of cellular telephone only service (and cellular telephone mostly service) households in addition to landline telephone service households will further assist in maintaining the representativeness of the survey sample to the general population.

Questionnaire Administration
How a question was written and which questions preceded it in the questionnaire could influence responses in unpredictable ways. Not all the questions used in the survey had been tested to ensure that all persons understand the intended meaning. Those that come from modules created by the Centers for Disease Control and Prevention usually had been tested, while some of the questions in state modules were not tested. Furthermore, not all questions were equally easy for respondents to answer. While it might be easy for a respondent to provide a personal opinion, it might be much harder to recall a past event (last mammogram) or provide factual information (household income).

Interviewers are trained and monitored to ensure that they administered the survey in a neutral voice and read the written question verbatim and without comment. Nonetheless, it was possible for the interviewer to bias the results through tone of voice or administration technique. Coding errors might also occur if the interviewer types in the wrong response to the question. In addition, the person being interviewed might alter his or her response to give the interviewer the most socially acceptable answer. This might be a problem especially for questions which might have a perceived stigma (e.g., HIV risk).

Response Rate
The bias from non-response could not be removed and it was not possible to know if those who
refused to respond would have answered the questions in approximately the same ways as those who responded.

**Confounding and Causation**

Personal characteristics which were presented in this report were univariate (i.e., examine each risk factor in relationship to only one characteristic at a time); however, the complexity of health associations were not fully represented by examining single relationships. For example, an examination of diabetes and employment status might show a greater prevalence of diabetes among persons who were retired than among persons who were employed. However, retired persons were expected to be older than persons who were employed; consequently, this relationship might entirely disappear if we controlled for the effects of age, (if this was the case we would say that the relationship between diabetes and employment status was being confounded by age.)

Likewise, this report did not attempt to explain the causes of the health effects examined. For instance, BRFSS data might show a higher prevalence of heart disease among smokers, but one should not conclude from this that smoking causes heart disease. That smoking was indeed a causal factor for heart disease is apparent from a large body of scientific data, but that was not a conclusion that could be drawn from a cross-sectional survey such as this. Rather this was a "snapshot" of disease, risk factors, and population characteristics for adult residents of Kansas at a point in time.
